

NEPA Scope of Work System

This system turns a proposed-action intake into a contract-ready scope of work requirements package before a complete EA review package exists. It selects resource workstreams, builds an intake evidence graph, renders required and optional deliverables, exposes reviewer adjudication, and hands accepted packages forward into EA assembly planning.

Operational proof is grounded in current gate evidence and tracked proving intakes.

Planning model

The system reads structured proposed-action evidence and turns it into resource-specific work tasks, data needs, deliverables, assumptions, dependencies, acceptance criteria, reviewer roles, review timing, and signoff fields.

Review boundary

The package is upstream planning support: resource selection, evidence paths, and contract fields stay separate from compliance and legal conclusions.

From proposed action to resource scope

The package records how each proposed-action element and evidence reference triggers a resource area and how that resource area resolves to a resource scope. That keeps scope selection inspectable before specialist work is contracted.

Representative intake graph: 115 nodes and 134 edges connect project, proposed action, action elements, evidence refs, resource areas, selected resource scopes, required deliverables, and reference reports.

Defensibility shown

Every proposed-action-derived resource area is expected to keep the planning path: proposed action -> action element -> evidence ref -> resource area -> resource scope.

Review signal

Validation fails closed on unsupported resource areas, dangling graph edges, observed reports without proposed-action support, missing work content, and missing reviewer-facing package sections.

Turn resource screening into work statements

Resource scopes are not just labels. Each selected scope carries work tasks, data needs, required and optional deliverables, defensibility checks, assumptions, dependencies, acceptance criteria, reviewer role, review timing, and signoff fields.

Current scope library: 10 resource work templates. A representative package selects 10 scopes, all with contract fields, required deliverables, optional deliverables, and rendering checks passed.

What is inspectable

Scope records keep tasks separate from deliverables and keep assumptions, dependencies, acceptance criteria, reviewer role, timing, and signoff fields explicit for contracting review.

What this prevents

Optional deliverables cannot satisfy the required-deliverable gate, and selected scopes without contract fields fail validation before package use.

CAPABILITY 3 / EVALUATION, ADJUDICATION, AND HANDOFF

Close the planning loop before EA assembly

The operational lane validates intakes without writing outputs, runs the proving-intake eval, checks generated package renderings, exposes reviewer adjudication for unresolved planning items, and converts an accepted package into a downstream EA assembly checklist.
