

Make NEPA Review Risk Visible Early

The system is an auditable NEPA review engine, not a stand-alone visualization. It connects source material, authority, evidence, findings, and forest-plan readiness so WLG can identify review risk while the record can still be fixed.

Current Region 1 graph surface.

What the engine shows

- Applicable and screened-out authorities.
- The evidence path behind each finding.
- Forest Plan consistency support and profile readiness.
- Missing, stale, or unsupported source dependencies.

Why it matters

The system points reviewers to the record defects that drive delay: source gaps, unsupported claims, stale authority language, and forest-plan blockers.

Trace Every Finding to Governed Evidence

Each output is generated from governed sources. The trail runs from workbook scope and artifact hash to evidence span, source claim, authority decision, and finding.

Evidence trace

Every finding remains linked to source identity, text evidence, authority status, and generated output.

Backward checks test the finding against the record.

The trace exposes missing evidence, stale authority language, and unresolved applicability.

Outputs generated from the trace

Traceability model: the finding is the end of a chain, not a free-standing conclusion. The same path supports reports, QA replay, graph views, and reverse checks.

Source boundary

Workbook scope, exclusions, partitions, catalog records, and hashes determine which materials can support review logic.

Reverse check

Findings can be tested backward for unsupported claims, stale authority dependencies, missing support, unresolved applicability, and forest-plan gaps.

NEPA, USDA regulations, and forest plans in one graph

The Region 1 graph presents NEPA authority, USDA regulations and procedures, source evidence, review views, and forest-plan data as connected layers without collapsing them into one undifferentiated network.

Simplified Region 1 graph model

A reduced 3D view of the graph: separate layers, shared evidence paths, and readable depth.

Forest plans stay separate

Forest-plan profiles and components are represented as their own layer, with readiness linked into review context instead of mixed into NEPA authority.

Authority and evidence stay inspectable

NEPA and USDA authority remain visible beside source records and evidence traces so reviewers can inspect the basis for a finding.
